# Sage-Grouse Breeding Lek Ahead

Sage-grouse gather every April at traditional breeding sites called "leks." This lek above Reservoir Creek has been regularly observed since 1961, but has probably been active much longer.

By observing carefully from your vehicle you will see the large black-and-white males displaying their fitness to visiting females by defending territories near the center of the lek with calls, posturing and brief fights. Leks are most active at dawn.

After breeding, females lay and incubate 5-8 eggs in a ground nest for 26 days, and guide their young to safe feeding areas throughout the spring and summer.

Individual sage-grouse may use hundreds of square miles of habitat annually. They need healthy sagebrush for food, shelter, and their continued survival.

Please dim your lights and park at the designated location ahead. To minimize disturbance remain quiet, do not leave your vehicle, and do not attempt to approach birds closer for photographs.

# Sage-Grouse Breeding Lek Ahead

## SAGE GROUSE

(*Centrocercus urophasianus*)

**OTHER NAMES:** Sage hen, sage cock, sage chicken. **CHARACTERISTICS:** The largest of Montana's grouse. Both sexes have relatively long, pointed tails, feathered legs, and mottled gray-brown, buff, and black plumage. Males have a blackish brown throat patch and an inconspicuous yellow eye comb. Both sexes have blackish bellies which contrast sharply with white under-wing coverts when the birds are in flight. Females appear to dip from side to side while flying. Adult males range from 26-30 inches in length and 4-7 lbs. in weight; adult females range from 19-23 inches in length and 2.5-3.5 lbs. in weight. **HABITAT:** Sagebrush. **SIMILAR SPECIES:** A female pheasant can possibly be confused with a female or young male sage grouse. Female pheasants, however, have a brown belly and bare legs, while female sage grouse have a black belly patch and feathered legs. **STATUS:** Native to Montana. Fall hunting season, both sexes.
